

# Cires®

Effective Vibration Insulation for all Kinds of Machines

## Cires<sup>®</sup> Versions

### General

When using resilient standard elements with approximate constant spring rate – e.g. steel springs, PU foams, cylindrical rubber buffers – the problem is that the tuning frequency of a machine's resilient support depends on the load applied.

In order to achieve a certain tuning frequency the loads of all components must be known. To avoid overloading of individual spring elements a resilient support using such elements must be designed by an expert. The position of the bearings has to be determined fairly exactly.

This requires a relative high effort concerning the support of e. g. an air conditioning system.

CIRES<sup>®</sup> elements show a property which especially favoures them for this kind of structural task. With CIRES<sup>®</sup> a constant tuning frequency can be achieved within an extensive load range.

Picture 1: CIRES<sup>®</sup>, Type Birdie

Picture 2: CIRES<sup>®</sup>, Type Eagle

Picture 4: CIRES®, Deflections referred to the Load per Element

Positioning and mounting of the elements is rather simple. It is sufficient to know the total weight of the machinery and of the foundation, if existing.

The position of the individual parts of the machinery to be resiliently supported as well as the one of the foundation is almost meaningless due to the high flexibility of the CIRES<sup>®</sup> elements.

The number of elements required are determined by means of picture 5 and the approximate total weight of the mass to be insulated (machinery plus foundation slab if existing). The CIRES<sup>®</sup> elements easily level uneven floors.

Due to the special CIRES<sup>®</sup> properties it is not necessary to pay too much attention to their exact positioning.

In case the load of the machinery is unevenly distributed over the foundation slab, the CIRES<sup>®</sup> elements simply are moved towards the heavier loads. Then the machinery is put in place.

**Note:** Horizontal forces must not be absorbed by Cires<sup>®</sup> elements but by additional structural measures.

# Cires<sup>®</sup> Insulating Effect

Technical Data		
Туре	Eagle	Birdie
Length	250 mm	250 mm
Width	250 mm	250 mm
Thickness	125 mm	60 mm
Natural Frequency	5 Hz	7 Hz
Load/Element	200-1600 kg	200-1600 kg

For the type Birdie the effect of protection against vibration begins with a frequency of 10 Hz. For frequencies of 20 Hz and higher an optimal protection against vibration with an effect of at least 15 dB is achieved. For the type Eagle the corresponding frequencies are 7 Hz and 15 Hz respectively. As regular rpm of e. g. an air conditioning are at 25 Hz, for this a support with type Birdie is entirely sufficient. Due to the low natural frequencies of 7 Hz and 5 Hz respectively, the elements are also suitable for machines running relatively slowly.
